SUBJECT: Savenac Nursery, Soil Nutrient Analysis

TO: District Ranger, Superior RD

On October 2, 1991 the soils within the fenced area at the Savenac Nursery Site were sampled to determine the chemical makeup and determine if there were any elements that were in short supply for plant growth or at toxic levels.

The soils are developed in nearly level step-like alluvial benches with short steep descending slopes called risers along one side. The riser at this location is outside of the fenced area with vertical relief of the riser at approximately 50 feet. Surface layers are sandy loam and loam with substratum materials of sand and gravel. The permeability is moderate and the watertable is very deep.

The pH of all samples range from 6 to 7.3 which is an excellent spread for plant nutrients because all are readily available within these ranges.

The analysis does point out an interesting item: The Phosphorus levels in all samples are extremely low. Most likely the origin of the landform has had a great deal to do with the actual amounts. In order to keep phosphorus from being a limiting factor it will be important to add it to the system as a fertilizer. Rock Phosphate should be a consideration to give a long-term effect.

Looking at the trace elements analyzed, the combination is adequate to provide for all necessary functions and thus are not limiting.

Nitrogen fertilizer applications will almost always show a flush of growth but these effects are not long lasting, so to maintain such types of responses, applications would be needed annually.

If there are additional questions, please contact me.
